Abstract

In this assignment we use the trained RNN model exploiting the temporal relationships of the characters present in the sequence. We train the model with the target as the next character in the sequence for 200 epochs. The RNN model automagically recognizes the temporal relationships of the characters in the sequence and generates features that can be used for inference predictions. The best part of the training is that we do not pre-process the data in any form. We even let the $< start >$ and $< end >$ tags to be present in the file. Our model can even store this relationship , thereby ensuring proper formats of our target output file. Needless to say , it can even generate proper headers for the music file.

Introduction

In this paper we explore various configurations in RNNs for the purpose of generating sequences of music. The Recurrent Neural Network has a simple sequential model with SimpleRNN as the first layer of the model. We then add a dense layer with softmax activation on top of it . We start with a batch of sequence having length 25. The core reason that recurrent nets are more exciting is that they allow us to operate over sequences of vectors: Sequences in the input, the output, or in the most general case both.See figure 1 .The difference between $return\_sequence = True$ and $return\_sequence = False$ is that in the first case the network behaves as in the 5th illustration (second many to many) and in the latter it behaves as the 3rd, many to one. We proceed with $return\_sequence = true$ as we wish to exploit the batch size with keras functionalities.

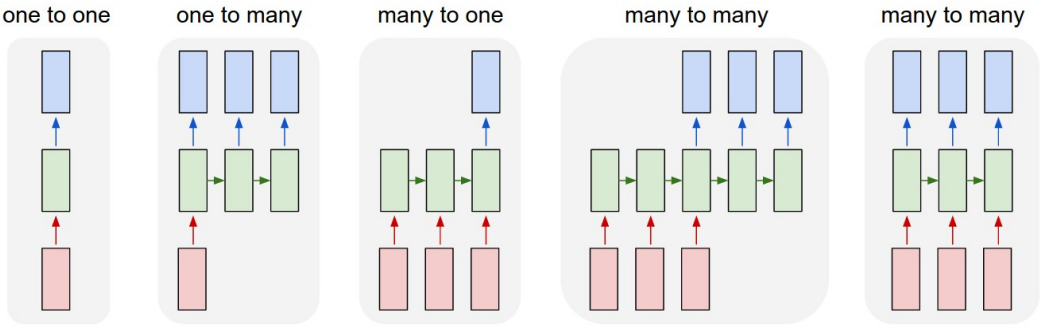

Figure 1: Various RNN configurations

a. Temperature

The ABC notation and the music representation generated from http://mandolintab.net/abcconverter.php are as follows:

- Temperature = 1
  The ABC notation for the sample 1 is shown in Figure 2
  The music representation for the sample 1 is shown in Figure 3
  The ABC notation for the sample 2 is shown in Figure 4
  The music representation for the sample 2 is shown in Figure 5

- Temperature = 2
  The ABC notation for the sample 1 is shown in Figure 6
  The music representation for the sample 1 is shown in Figure 7
  The ABC notation for the sample 2 is shown in Figure 8
  The music representation for the sample 2 is shown in Figure 9

- Temperature = 0.5
  The ABC notation for the sample 1 is shown in Figure 10
  The music representation for the sample 1 is shown in Figure 11
  The ABC notation for the sample 2 is shown in Figure 12
  The music representation for the sample 2 is shown in Figure 13

The tunes have been uploaded in midi format on vocareum (see folder PartA).

Discussion of Results:

- We generated 2 samples for each of the temperature parameter and observed that the samples generated for T = 0.5 were melodious and had the sequence of musical notations without skipping of notes.

Figure 2: Temperature = 1: ABC notation for Sample 1

Figure 3: Temperature = 1: Music representation for Sample 1

- We also observed that as we increased the temperature, the music was slower and skipped a few musical notations.
- Also, we observed that the tempo of the song was different for different temperature parameter.

The **hyper parameters** are as follows:

- Number of neurons in the hidden layer = 100
- Optimizer used = Adam
- Loss function used = Categorical cross entropy
- Mini batch size = 25
- Number of epochs = 100

Figure 4: Temperature = 1: ABC notation for Sample 2

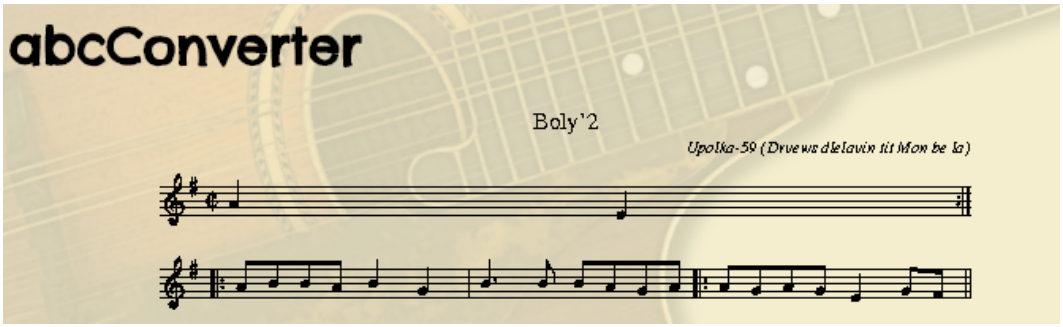

Figure 5: Temperature = 1: Music representation for Sample 2

- Figure 14 shows the variation of training and validation loss with epochs run on neural network with 100 hidden units.
- We observe that the train loss decreases with number of epochs. As expected, we see that validation loss is higher compared to training loss as at the time of validation it sees relatively new data. This reaffirms that neural network is learning on the data.
- We also observe that the validation loss roughly decreases with number of epochs, but with a slope less steeper than train loss.
- Validation loss doesn't exhibit a smooth trend like Train loss. The frequent variations in the validation loss can be explained because while calculating validation loss, we are testing on the unseen data.

c. Number of hidden neurons

Figures: 15,16

- Figure 15 shows the variation of training loss with varying number of hidden units between 50, 75, 100, 150
- Figure 16 shows the variation of validation loss with varying number of hidden units between 50, 75, 100, 150
- We observe that the training loss shows the same trend as we observed above for every choice of number of hidden units ie., training loss goes down with number of epochs

```

Figure 6: Temperature = 2: ABC notation for Sample 1

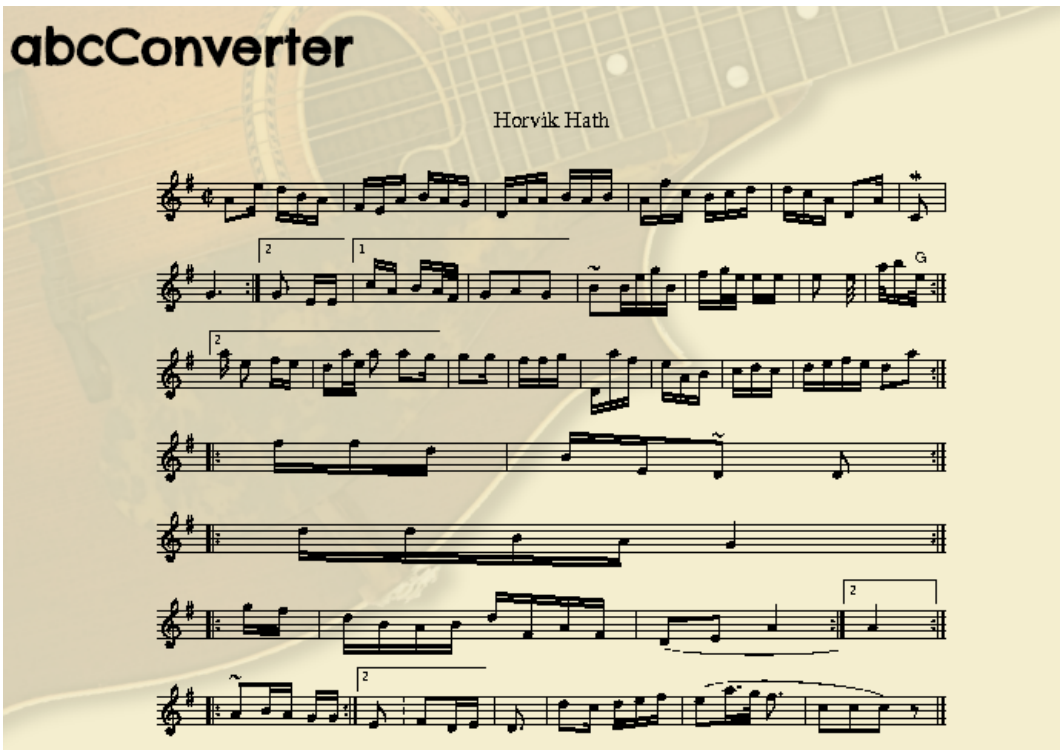

Figure 7: Temperature = 2: Music representation for Sample 1

- Secondly, we can also observe that the decrease in training loss increases as we increase the number of hidden units. In other words, training loss of 150 is better than 100 than that of 75 and so on.
- We observe that the validation loss shows a similar trend as we observed above for every choice of number of hidden units ie., the loss goes down with number of epochs (Except for the case when number of neurons is 150, we see a slight increase after 50 epochs which can be explained as a case of over fitting)
- A more interesting observation is comparing Validation loss across different number of neurons. We expected that validation loss to follow the same trend as train loss but our results show otherwise.
- Firstly, we see that validation loss is less in the case of 75 neurons and increases for 100 neurons, which explains that with 100 neurons we are likely to over fit the data than when we have 75 neurons. The graph shows that the sweet choice of number of neurons is 75
- Secondly, we also see that in the case of 150 neurons even though it has the minimum validation loss initially, it quickly increased after 50 epochs and started to perform worse than 75 hidden units. The reason again, can be attributed to over fitting the overwhelmed network with lots of parameters.

d. Dropout

The dropout technique is a data-driven regularization method for neural networks. It consists in randomly setting some activations from a given hidden layer to zero during training. Repeating the procedure for each training example, it is equivalent to sample a network from an exponential number of architectures that share weights. **Figures: 17,18,19,20**

- We added a drop out layer after the Simple RNN layer in our model. We used the same model for calculating the training and validation accuracy.
- We observed that both the training18 and validation20 accuracy decreased as the drop out was increased.
- We also observed that the training17 and validation20 loss increased with the increase in the drop out rate.

Figure 10: Temperature = 0.5: ABC notation for Sample 1

Figure 11: Temperature = 0.5: Music representation for Sample 1

- We observed that the time to run an epoch started varying with the epochs. The epoch were run in 16-19s while with out dropout, the time to run an epoch was mostly consistent. Though, we found that the dropout did not significantly affect the training speed. It still took us approximately the same time ($\sim$17-18s) to train our model for an epoch.
- The observed results were quite close to the results that we got without dropout.

e. Optimization techniques

Figures: 21,22

- We have plotted training 21 and validation loss 22 for the following optimization techniques: Adagrad, Adam, RMSprop
- We see that Adam and RMSProp have comparable performances for our application than Adagrad. We can see the similar trend for both training loss and validation loss as observed in the previous part. Adagrad performs poor convergence due o slow learning rate. Adam seeks to reduce its aggressive, monotonically decreasing learning rate. Instead of accumulating all past squared gradients

Figure 13: Temperature = 0.5: Music representation for Sample 2

f. Feature Evaluation

We observed the activations of a neuron for a single sequence and observed the heatmaps as can be seen in figure 23 . The heatmaps show us a pattern in which the music of a song show similar variation in the heat. That is, these delimit some notion of music that we as music novice find difficult to interpret. The heatmaps provide us a medium to get better insight into the functioning of the RNN model .

1 Learning and Results

We learned that RNN possesses great power to not only predict next character in the sequence but can also generate music at its own behest without much triggering. This shows us the enormous capacity of RNNs to do feature engineering across time. The natural algorithms like BPTT take care of the shared weights learned across time. And hence provide us a learned model.

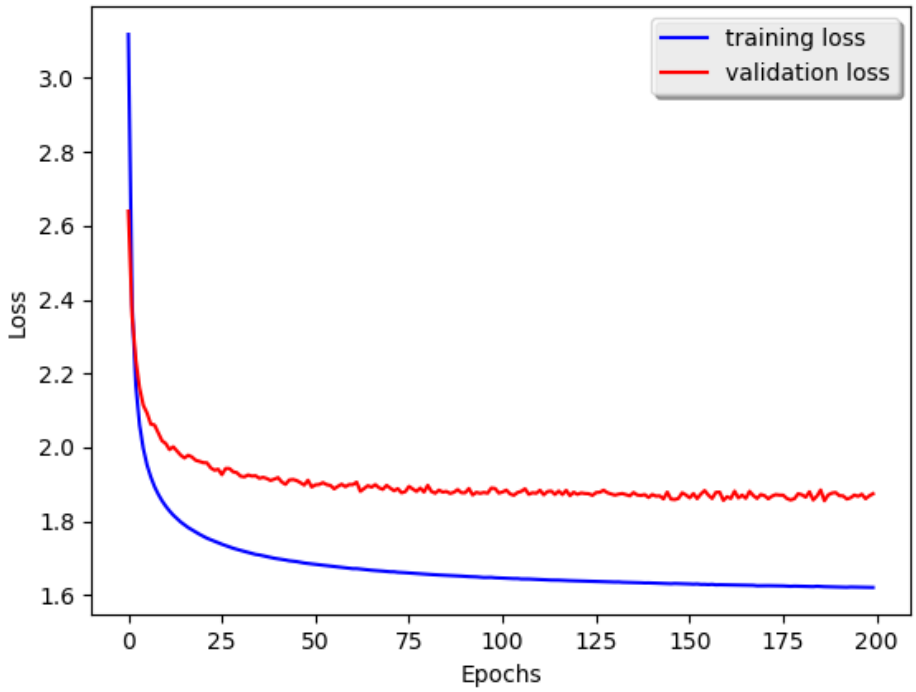

Figure 14: Train and Validation loss variation with epochs

Table 1: Contribution by each team member

S.no.	Name	Contribution
1	Swapnil Taneja	Code implementation and experimented with feature evaluation
2	Saksham Sharma	Code implementation and experimented with temperature parameter
3	Kriti Aggarwal	Code implementation and experimented with dropout parameter
4	Prahal Arora	Code implementation and experimented with the number of neurons
5	Saicharan Duppati	Code implementation and experimented with different optimization techniques

2 Contributions

We made sure that most of the work is equally distributed and shared our individual contributions for the team assignment, so that each of us understood the latters work. Following are roughly the contributions made (see Table 1.):
